Here, the first-order derivative has been used to solve the second-order reaction-diffusion equation, namely the time-fractional reactive diffusion equation. In this research, we have used the trial and error method to solve for the unknown parameter in the general form. After obtaining the exact solution, the importance and future research direction of the time-fractional reaction-diffusion equation have also been discussed. This is a finite difference approach, and the results obtained can be applied to a wide range of research areas such as fiber optics and integrated optics, molecular engineering, nanoscale devices, and biophysics. In this report, we have studied the various properties of fractional Laplace operator (F-Laplacian) and obtained the fundamental solutions for this operator. The solution of fractional Laplace equation is obtained by using the transformation method and the series expansion. In one approach, the square root and square property of fractional Laplacian are derived and the maximum and minimum principle are obtained. Also, we have found that this operator represents the fractional relaxation in a fractional Laplace equation. Then, the Gauss--Green kernel is obtained and compared with that of the Riemann--Liouville fractional Laplacian. As an application, the F-Laplacian is used to derive the required solutions for the time-fractional reaction-diffusion equation. In this paper, we propose an approximate solution to the Riemann-Liouville generalized fractional heat equation. For this purpose, we first established a theoretical relation between the generalized fractional heat equation and a class of coupled nonlinear differential-difference equations. Then we find the auxiliary function and the solution. Finally, by utilizing our obtained results we investigated the time-fractional heat equation and extended the analytical solution of time-fractional heat equation. The theory and numerical results were presented graphically and discussed.
